

# THE VEGETATION OF THE NORTHERN SLOPES OF THE GOG RANGE

Phil Barker, Consultant  
C/o Dept of Geography and Environmental Studies  
University of Tasmania

September 1992

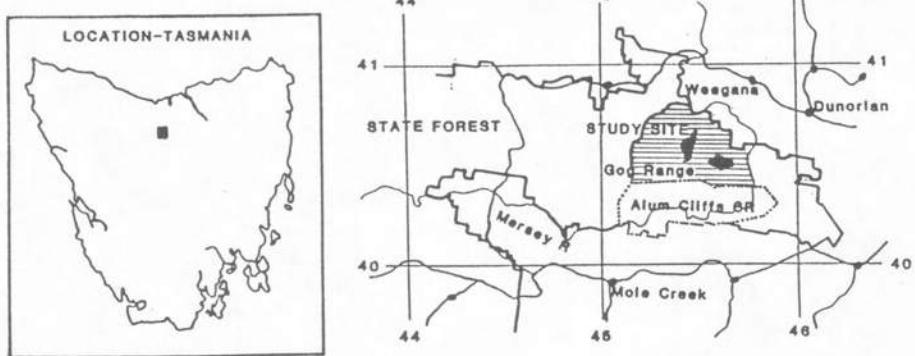

TECHNICAL REPORT 1992/3

QUEEN VICTORIA MUSEUM AND ART GALLERY  
LAUNCESTON

A Vegetation Survey of the Northern Slopes  
of the Gog Range, Tasmania.

March 1992.

Consultant. Phil Barker  
c/o Department of Geography and Environmental Studies  
University of Tasmania

The regional location of the study area.

## ACKNOWLEDGEMENTS

The assistance of Mary Cameron and Tim Kingston from the Queen Victoria Museum is gratefully acknowledged as are the contributions of Jasmyn Lynch and John Duddley. Help with the identification of species was generously volunteered by Dennis Morris and Alex Buchanan of the Tasmanian Herbarium, Hobart. The cooperation of the Forestry Commission, Tasmania, in postponing logging operations for the duration of the survey is acknowledged and appreciated. A very special thanks to Jim Nelson and Claudia Nelson for their hospitality and keen interest, and for sharing local knowledge during the period of this survey. Funding for this project was provided by the Plomley Foundation.

## Summary and Recommendations

A total of 241 species were positively identified in the present survey. This comprises 155 dicotyledons, 49 monocotyledons and 37 ferns and fern allies. The most common species are *Eucalyptus amygdalina* and *Eucalyptus obliqua* as dominants; *Acacia melanoxylon*, *A. mucronata*, *Exocarpos cupressiformis*, *Monotoca glauca* as subdominants, and *Pultenaea juniperina*, *P. gunnii*, *Daviesia latifolia* and *Lomatia tinctoria* in the shrub layer. *Gonocarpus* spp., *Tetratheca pilosa*, *Viola hederacea*, *Goodenia lanata*, *Lagenophora stipitata*, *Geranium potentilloides*, *Hydrocotyle sibthorpioides* and *Poa rodwayi* are also very widespread. *Pteridium esculentum* occurs in every community. The suite of common species shared between communities makes community differentiation unclear in some areas and so only major units have been mapped.

The most apparent controls over the vegetation are the geological sequence from south to north and the narrow catchments separated by narrower ridges in the north of the study area. These features are reflected in the vegetation in the form of east-west belts associated with the geology and north-south belts associated with ridges in the northern part of the study area. Obviously this is most conspicuous in the gully communities.

Narrow belts of shrubby sclerophyll forest exist on the ridges above non-sclerophyll riparian vegetation which supports a diverse fern flora. Up to 19 species of ferns were recorded in a single 400 m<sup>2</sup> quadrat (240). The most diverse fern floras are associated with the most diverse tree floras, and probably reflect the variety of microsites associated with these dominant species.

*Blechnum patersonii*, a rare ground fern, occupies a restricted area of habitat along the Eel Hole Creek and adjacent to logging coupe 1. This habitat is vulnerable to siltation from upslope and bank disturbance by increased stream flow. It is, therefore, essential to prevent excessive overland flow or increases in the stream flood peak. If the area were to be logged, stream-side reserves would need to be at least 40m wide on each side to adequately protect the fern flora within these belts from desiccation and the erosion products carried by overland flow. This has been already been suggested by Williams (1987).

Nothing is known of the ecology of any of the other rare species in the study area, and as such, specific management initiatives are difficult to recommend. It would, however, be prudent to avoid disturbance of the immediate areas containing those rare or unreserved species that were recorded only from a restricted area during the present study. The sites are marked on figures 4 and 6. The species include *Desmodium varians* var. *gunnii*, *Phyllota diffusa*, *Goodia pubescens*, *Blechnum patersonii*, *Ajuga australis*, *Poa* sp *nova* and *Uncinia elegans*. The remaining two rare species, *Pimelea curviflora* var. *gracilis* and *Poa tenera* are relatively wide spread in the study area.

Almost the entire sclerophyll forest area of the study area has been degraded by woodcutting and associated vehicle tracks. The disturbance generated by this practice facilitates opportunities for weed invasion. Opening of the forest canopy changes the environment of the forest floor by increasing insolation. More rapid drying of the ground and accumulated leaves and twigs than would otherwise be expected coupled with increasing use by humans with their chainsaws and vehicles poses an increased threat of fire. The ban on woodcutting should therefore be imposed more rigorously. A single gate may be appropriate.

## Introduction and Aims

The Gog Range is situated in the central north of Tasmania ( $146^{\circ} 28' E$   $41^{\circ} 34' N$ ) (figure 1). The range has an east to west alignment and is flanked by the Mersey River from the south-west through the south to the north-east quarter.

Part of the southern water-shed of the range is included in the Alum Cliffs State Recreation Area. The northern water-shed is State Forest. An extensive area in the north-west foothills has been converted to *Pinus radiata* plantation. It is proposed to clear-fall and regenerate much of the remaining forest.

The aim of this survey is to intensively sample two proposed logging coupes on the northern foothills (figure 3) and to extensively survey an additional area of approximately  $18 \text{ km}^2$  which represents the remainder of the northern slopes of the Gog Range.

This report covers the area of the remaining native forest on the northern slopes of the Gog Range. It records all species collected and describes the communities in which they exist. The conservation status of species and communities are determined and discussed. Communities are mapped at the maximum resolution possible from 1:20,000 aerial photography and ground verification based on quadrat data.

## Climate

The climate is described as perhumid cool (Gentilli 1972). Snowfalls are common on the range in winter but snow does not usually lie on the ground for more than a few days. Winter also produces frequent frosts in the foothills and a moderate rainfall maximum. Temperatures above  $30^{\circ} \text{C}$  are only very occasional each summer.

## Geology (Figure 2). (Reference. Jennings (1979))

The Gog Range is composed of Ordovician Roland conglomerate. This quartz conglomerate and is up to 300m thick. Immediately below the cliff faces of Mount Gog a quartzite and conglomerate talus extends along the length of the range. In steeper areas the talus is unstable and its influence extends down-slope considerably, affecting soil properties on other rock types. In the west of the study site, the conglomerate and the talus is succeeded by purple minnow keratophyre; this is the only exposure in the region.

On the lower slopes of the Gog Range the Gog Range Greywacke is extensive and covers the greater area of the study site. The Gog Range Greywacke represents a period of deposition with low level volcanic activity. This sequence is at least 600m thick. In most areas the formation contains volcanic members. These rocks are usually acid and related to the keratophyre.

The Minnow Keratophyre overlays the Greywacke and is itself overlain by the conglomerate. The formation consists of soda-rhyolite, keratophyre and tuff.

A small area along the Mersey River in the east of the study site is Recent alluvium. These deposits are dominated by boulders and cobbles in a clayey or sandy matrix.

## Methods

The survey was designed to sample the study area using stream water catchments as the basis for the sampling strategy. This sampling strategy is superior to random stratified or regular grid-based strategies because the systems approach is able to conform to, and sample, variability in the landscape more readily.

The study area was divided into eleven catchments which included first, second and third order streams. The catchments vary in area from about  $1 \text{ km}^2$  to  $2.5 \text{ km}^2$  (Figure 3).

Ridgelines, midslopes and gullies were all sampled, and different aspects were sampled at similar altitudes or slope positions. Quadrats of 400 m<sup>2</sup> were used as the basic survey unit. All trees and shrubs within this area were recorded. Herbs, graminoids and grasses were sampled at 3 randomly located subplots each measuring about 4 m<sup>2</sup>. Species noted outside of the sampling quadrats were included in the community list as present, otherwise abundance measures and status were attributed as:

1. Dominant in the stratum in which the plant occurs - tallest and most abundant.
2. Common - regular to abundant but not the dominant species.
3. Sparse - more than one but relatively few individuals present.
4. Isolated - only one recorded in the quadrat.

Community classification of the quadrat data was achieved by comparison of species lists to existing Tasmanian classifications.

Species nomenclature follows Buchanan *et al.* 1989.

## The Communities (See Table 2. Communities by quadrats)

### Dry sclerophyll forest

#### A. Grassy *Eucalyptus amygdalina* forest

This forest type is restricted to the far north-east of the study area and was sampled in only two quadrats, 434 and 442. The forest is dominated by *E. amygdalina* with sparse *Acacia melanoxylon* and *Exocarpos cupressiformis* as subdominants. Small shrub species typically less than 30cm tall include *Acrotriche serrulata*, *Pultenaea gunnii* var. *baeckiioides*, *Hovea heterophylla*, *Epacris impressa* and *Bossiaea prostrata*. *Lomandra longifolia* dominates above this level. The straggling peas, *Glycine clandestina* and the vulnerable *Desmodium varians* var. *gunnii*, can be found amongst the ground layer. Grasses are common throughout and include *Poa rodwayi*, *Danthonia pilosa*, *D. penicillata*, *Dichelachne rara*, *Deyeuxia monticola*, *Echinopogon ovatus*, *Ehrharta stipoides*, *Poa labillardieri* and *Themeda triandra*.

#### B. Shrubby *Eucalyptus amygdalina* forest

This occupies the north facing ridgelines and associated north-western slopes to about midslope level on soils derived from greywacke in the north of the study area (figure 5). This community is dominated by *E. amygdalina* sometimes with *E. obliqua* or *E. viminalis* co-dominant at 15 to 25 m and is **poorly reserved**. A subdominant stratum is present in some quadrats, but not all. It is composed of *Banksia marginata*, *Exocarpos cupressiformis* or *Acacia dealbata* may occur. *Lomandra longifolia* is common and dominates the low shrub level. Shrubs at the same level are sparse and most often include *Lomatia tinctoria*, *Pultenaea juniperina*, *P. gunnii* and *Epacris impressa*. The ground layer is peculiar in its diversity of prostrate or low cushion-like shrubs. These are typically represented by abundant *Acrotriche serrulata* and *Hibbertia serpyllifolia* but also common are *Hovea heterophylla*, *Bossiaea prostrata*, *B. cordigera* and *Astroloma humifusum*. The litter load can be subjectively estimated as low with bare ground and fragmented Greywacke occupying 5-10% of the surface. The position of this habitat in the landscape ensures that it receives perhaps the highest radiation while also having the most restricted catchments of any community. Consequently it is likely to be the driest community in the study area.

#### C. *Allocasuarina littoralis* woodland

This community occurs on dry western slopes in the north of the study area. It normally occupies the midslope position below the shrubby *Eucalyptus amygdalina* forest and sparse *E. amygdalina* and *E. obliqua* may occur throughout. *Exocarpos cupressiformis* is also important and in some cases co-dominant. *Banksia marginata* and *Notelaea ligustrina* are also conspicuous and common. *Bursaria spinosa*, *Acacia melanoxylon* and *Pomaderris apetala* appear to be adventive from gully communities below and are sparsely scattered. The understorey is often sparse and heathy being composed of small shrubs such as *Lomatia tinctoria*, *Persoonia juniperina*, *Pultenaea juniperina*, *P. gunnii* var. *baeckiioides*, *Hibbertia serpyllifolia* and *Epacris impressa*. *Tetratheca pilosa*, *Oxalis corniculata*, *Goodenia lanata*, *Poranthera microphylla* and *Billardiera scandens* appear regularly but are all sparse as are *Lomandra longifolia*, *Dianella revoluta* and *Lepidosperma laterale*. The native grasses *Poa rodwayi*, *Danthonia pilosa* and *D. penicillata* are frequent but similarly do not produce more than a sparse cover.

#### D. Shrubby *Eucalyptus obliqua* open forest (Type 1.)

*Eucalyptus amygdalina* shares dominance with *E. obliqua* but is not present in the same density. *Acacia mucronata* is a common subdominant and *A. dealbata* and or *A. verticillata* may also be present. *Bedfordia salicina* and *Olearia lirata* are sparsely scattered through the community. The shrub layer is quite depauperate even in areas where *Pteridium esculentum* does not dominate and is usually represented by abundant *Pultenaea juniperina*, with *P. gunnii* var. *baeckiioides*, *Billardiera scandens*, *Lomatia tinctoria* and *Epacris impressa*. The ground cover is sparse but quite diverse and includes *Drymophila*

*cyanocarpa*, *Gonocarpus tetragynus*, *Goodenia lanata*, *Viola hederacea*, *Geranium potentilloides*, *Oxalis corniculata*, *Hydrocotyle sibthorpioides* and *Lagenifera stipitata*. Grasses and graminoids are rare. In broad depressions between ridges the ground fern *Culcita dubia* is often abundant in place of *Pteridium esculentum* and dominating the stratum.

The community grades into *Eucalyptus obliqua* / *Eucalyptus amygdalina*-*Monotoca glauca* open forest on the siliceous fan below the conglomerate talus. This *E. obliqua* shrubby forest is clearly transitional toward wetter forest types. This community occupies an extensive area in the study area and is characterised by *E. amygdalina* and *E. obliqua* as co-dominants. *E. amygdalina* sometimes assumes single species dominance on low ridges. The area faces north on slopes of 3 - 7 degrees. The most conspicuous floristic feature of this forest is the subdominance of *Monotoca glauca* as a small tree up to 5m tall. *Acacia mucronata*, *Leptospermum scoparium*, *Banksia marginata* and *Exocarpos cupressiformis* are occasional but may form a mid-dense canopy with *M. glauca* and *Oxylobium arborescens*, and *Acacia verticillata* replacing *A. mucronata* in the heads of bowls between low ridges and along creeklines. *Pteridium esculentum* is often abundant across extensive areas. It is suggested that abundant *Pteridium* indicates regular burning (Duncan and Brown 1985) but this view may be somewhat dogmatic as areas of free drainage may also indicate *Pteridium*'s prime habitat. Shrubs of *Pultenaea juniperina*, *Lomatia tinctoria*, *Aotus ericoides*, *Epacris impressa* and *Persoonia juniperina* are sparsely scattered over *Gonocarpus teucrioides*, *Tetratheca billardiera*, *T. pilosa* and *Stylium graminifolium* which are also sparse. Herbs are rare but include *Viola hederacea*, *Goodenia lanata*, *Lagenifera stipitata*, *Geranium potentilloides*, *Helichrysum scorpioides* and *Hydrocotyle sibthorpioides*.

**Type 2.** A floristically more depauperate version of this community in which the shrub layer is completely dominated by *Daviesia latifolia* occurs predominantly in the north-east of the study area along broad ridges and their higher slopes but also on the Keratophyre geology in the west.

#### **E. Heathy *Eucalyptus amygdalina* woodland**

This community is on talus and talus wash derived from conglomerate possibly over richer greywacke. This is reflected in the change of vegetation formation to the west where the community gives way to heathy scrub on deeper talus. *Eucalyptus amygdalina* dominates to a height of 20m. *Leptospermum scoparium* and *L. glaucescens*, *Monotoca glauca* and *Banksia marginata* are common while *Oxylobium arborescens* is locally frequent in scattered pockets. *Pteridium esculentum* can be abundant, but where it is not the heath species such as *Aotus ericoides*, *Persoonia juniperina*, *Boronia pilosa*, *Xanthosia ericoides*, *Leucopogon collinus* and *Epacris impressa* are sparsely scattered amongst the *Pteridium esculentum*, *Lomandra longifolia*, *Pultenaea juniperina*, *P. gunnii* and *Tetratheca glandulosa*.

#### **Wet sclerophyll communities**

#### **F. *Eucalyptus obliqua* Tall Open Forest. OB0110 (Kirkpatrick et al. 1988) (Quadrats 458, 473, 466, 238, 4, 5, 25, 203)**

This community is considered to be both common and widespread (Kirkpatrick et al. 1988). In the study area it occurs from mid to lower slope positions usually adjacent to creek lines on a range of aspects but in the most protected situations. In all but one case in the study area *Eucalyptus obliqua* is dominant at a height of about 40m with a single occurrence of *E. regnans* co-dominance. *Acacia dealbata* and or *A. melanoxylon* are subdominant and emergent over a dense canopy at about 10 to 15m. The dense canopy is composed of *Pomaderris apetala*, *Olearia argophylla* and occasional *Bursaria spinosa* with *Bedfordia salicina* at the margins. A fairly sparse lower tree layer at about 4m supports *Zieria arborescens*, *Coprosma quadrifida* and *Beyeria viscosa*. *Cyathodes glauca* and *Pimelea drupacea* also persist as sparse understorey shrubs. The tree-fern *Dicksonia antarctica* is common although it is replaced by *Cyathea australis* in the *E. regnans* association. The

remaining fern flora is scattered but quite diverse and most quadrats contain *Hymenophyllum cupressiformis*, *Histiopteris incisa*, *Rumohra adiantiformis*, *Microsorium diversifolium*, *Pteridium esculentum*, *Hypolepis rugosula*, *Polystichum proliferum*, *Blechnum wattsii*, *Tmesipteris billardieri*, *Asplenium bulbiferum* and *Grammitis billardieri*. Where this forest reaches a senescent stage the eucalypts and Acacias are very sparse above an understorey which appears to be self perpetuating although simplifying floristically. The small trees, *Bedfordia salicina* and *Olearia argophylla* become less frequent while the *Pomaderris apetala* appear to be resprouting and the *Beyeria* and *Coprosma* may be regenerating continuously. Most of the remaining components such as *Pimelea*, *Cyathodes* and the ground fern species are evident in treefall gaps.

#### **G. *Eucalyptus obliqua* OB010 (Kirkpatrick et al. 1988).**

This community is found on higher slopes and is transitional toward shrubby *E. obliqua* forest. The community is dominated by *E. obliqua* but may also support one or both of *E. viminalis* and *E. amygdalina*. *Bedfordia salicina* is often subdominant although occasional *Acacia* spp. may overtop it. These may vary dependant upon the adjacent community and include *Acacia dealbata*, *A. melanoxylon*, *A. mucronata* and *A. verticillata*. Common shrubs are *Lomatia tinctoria*, *Pultenaea juniperina*, *Olearia lirata*, *Cyathodes glauca* and *Cassinia aculeata*. Herbs are also present and include most commonly *Acaena novae-zelandiae* and *Viola hederacea* and more sparse *Hydrocotyle* sp., *Poranthera microphylla*, *Gonocarpus tetragynus*, *Drymophila cyanocarpa*, *Geranium potentilloides* and *Oxalis corniculata*. In some situations *Pteridium esculentum* may dominate the fern layer.

#### **H. *Eucalyptus obliqua* mixed forest**

This is the only mixed forest community in the study area and is not described by Kirkpatrick et al. (1988). This type is very restricted in the study area being sampled only at quadrat 478. In a similar manner to the former community this one is restricted to a creekline in a broad shallow gully. *Nothofagus cunninghamii* and *Atherosperma moschatum* are subdominant. The understorey trees include *Pomaderris apetala*, *Phebalium squameum* and *Beyeria viscosa*. Common shrubs are *Pomaderris pilifera*, *Olearia lirata*, *Aristotelia peduncularis* associated with *Gahnia grandis*. The most common fern is *Blechnum wattsii* mixed with *B. nudum*, *Sticherus tener*, *Polystichum proliferum* and *Histiopteris incisa*. *Gleichenia dicarpa* is patchy while the shrubs *Pimelea drupacea* and *Coprosma quadrifida* are rare.

#### **I. *Eucalyptus obliqua* OB0111 (Kirkpatrick et al. 1988)**

This community is very restricted and was only sampled at one quadrat (406). It has been distinguished from the other *E. obliqua* wet forests on the presence of *Phebalium squameum*. The community occurs along an upper tributary of the Eel Hole Creek which drains the siliceous talus area to its south. *Acacia melanoxylon* is subdominant. *Zieria arborescens* is abundant and *Acacia mucronata* and *Monotoca glauca* are common understorey associates. The ground stratum consists of ferns including common *Pteridium esculentum* and *Blechnum wattsii* but also *Histiopteris incisa*, *Hypolepis rugosula* and isolated *Dicksonia antarctica*.

#### **J. *Eucalyptus viminalis* open forest, VIM0100 (Kirkpatrick et al. 1988).**

This wet sclerophyll forest community is widespread in the north and east of the state but is very restricted in the study area. *Eucalyptus viminalis* is associated with *E. obliqua* to about 30m tall on south-eastern aspects on moderate to steep slopes adjacent to creeklines. *Acacia melanoxylon* is usually a common emergent over a dense canopy of *Pomaderris apetala* and *Olearia argophylla*. Common shrub species include *Olearia lirata* and *Coprosma quadrifida* with sparse *Pimelea drupacea* and *Lomatia tinctoria*. The ground ferns *Pteridium esculentum*, *Blechnum nudum* and *Polystichum proliferum* are usually common but epiphytic fern species are rare. *Viola hederacea*, *Oxalis corniculata* and *Geranium potentilloides* are scattered as a very sparse ground cover. The orchids *Chiloglottis* sp. and *Acianthus* sp. are common around animal diggings. In a similar manner to other wet

sclerophyll communities in the study area *Bursaria spinosa* and *Bedfordia salicina* are often subdominant at the uphill margins of this community.

#### **K. *Eucalyptus viminalis* tall open forest, VIM0011 (Kirkpatrick et al. 1988)**

One quadrat (428) is closely related to this type which otherwise is restricted to rocky sites on the Western Tiers. In the present study, the community is distinguished by its higher number of herb species. This probably indicates its transition toward the dry sclerophyll association between *E. viminalis* and *E. amygdalina*. This locality supports a tall open forest in which *Acacia melanoxylon* is subdominant. *Bursaria spinosa* is common amongst the small tree stratum and *Pomaderris apetala* is a more sparse associate. *Cassinia aculeata*, *Olearia lirata* and *Coprosma quadrifida* are under-shrubs and *Pultenaea juniperina* and *Lomatia tinctoria* are common smaller shrubs. *Pteridium esculentum* is present as a fern layer over the herbs *Viola hederacea*, *Acaena novae-zelandiae*, *Oxalis corniculata*, *Geranium potentilloides* and *Gonocarpus tetragynus*.

### **Riparian communities**

#### **L. Pomaderris closed forest**

This community is best described structurally as a low closed forest. It is distinguished from its wet sclerophyll relatives on the basis of the sparse, adventive nature of eucalypts. The forest is broadleaf and not sclerophyll. The community typically occupies a narrow belt along small streams and often extends up to the midslope position. It may occupy more extensive areas where stream flats occur in shallow valleys between ridges and at stream confluences at the toes of spurs. The closed canopy of 10 - 15m is composed of *Pomaderris apetala*, often to the exclusion of any other species. *Olearia argophylla* may be occasional at the stream bank where additional light possibly eases the competition from the vigorously growing *P. apetala*. Occasional *Acacia melanoxylon* or *A. dealbata* are sparse emergents and *Pittosporum bicolor* may be sparsely scattered throughout at some sites. *Coprosma quadrifida* is common although etiolated in the otherwise very depauperate shrub layer. *Pimelea drupacea* tends to occur at the stream banks. The ground layer is quite variable in this community but typically *Lepidosperma elatius* is common if stream flats are present otherwise *Polystichum proliferum* and *Blechnum nudum* are predominant. Where the community occupies steep slopes the ground cover is very sparse supporting only occasional *Oxalis corniculata*, *Clematis aristata* seedlings, *Hydrocotyle javanica*, *Viola hederacea* and rare *Australina pusilla*. The fern flora remains quite rich being supported as epiphytes which include *Hymenophyllum* spp., *Rumohra adiantiformis*, *Asplenium terrestris*, *A. bulbiferum*, and *Grammitis billardieri* plus the ground fern *Blechnum wattsii*. The stream line itself may support *Dicksonia antarctica* and its associated epiphytic ferns, *Tmesipteris billardieri* and *Microsorium diversifolium*. Where the stream broadens slightly and the flow slows the King fern *Todea barbara* dominates the sandy stream bed. At the upslope margin of this community *Bedfordia salicina* and/or *Bursaria spinosa* are often subdominant to eucalypts.

#### **M. Atherosperma-Beyeria closed forest**

*Atherosperma moschatum* is common and forms a mid-dense canopy while *Beyeria viscosa* is predominant amongst mixed small tree species including *Pomaderris apetala* and *Bursaria spinosa*. It is this association of co-dominants which distinguishes this community from Sassafras-Musk rainforest described by Jarman et al. (1991). Generally, Eucalypts are absent, but emergent trees of *Acacia dealbata* are a common characteristic. In the shrub layer *Coprosma quadrifida* is most important and is common while *Pimelea drupacea* and *Correa lawrenciana* are more sparse. *Goodia lotifolia* may occur where the instability of the stream bank provides the disturbance necessary for its perpetuation. The fern flora is more diverse and more abundant than in the *Pomaderris* forest probably in response to the greater diversity of suitable microsites. *Dicksonia antarctica* supports *Tmesipteris billardieri*, *Microsorium diversifolium* and *Hymenophyllum* spp. plus *Ctenopterus heterophylla* and *Polyphlebium venosum*. Less specialist epiphytic ferns include *Rumohra adiantiformis*, *Asplenium terrestris* and *A. bulbiferum*. Ground ferns recorded were *Blechnum wattsii*, *B.*

*nudum*, *Polystichum proliferum*, *Lastreopsis acuminata* and *Hypolepis rugosula*. *Pellaea falcata* may be localised on rocky banks while *Histiopteris incisa* and *Pteridium esculentum* occur in disturbed areas or where the light levels are higher. This community is in a similar landscape position to the last community and it appears to be buffered from some fires by its environment and its own less combustible structure and floristics. Neyland (1991) described communities similar to this surrounding *Atherosperma* forest as rainforest buffers from which eucalypts were excluded even though fire is part of the community's ecology. It appears that eucalypts only enter the community as adventive species possibly after the occasional breach by fire or in gaps caused by mechanical disturbance. The community's own regeneration may be stimulated by mechanical disturbance produced when the tall eucalypts at the perimeter and the emergent Acacias fall and consequently open the canopy.

The rare fern *Blechnum patersonii* was found on stream banks in this community. Three populations were located in the Eel Hole Creek catchment. The largest was greater than 100 vigorous plants on the steep west-facing bank (quadrat 36) from 1m to 3m above the creek bed and extending for approximately 40m along the creek. Few other plants existed on the bank. At this location no *B. patersonii* were observed on the opposite bank which was not nearly as steep and supported thicker and more diverse vegetation at the ground level.

#### N. Myrtle-Musk rainforest. (See Jarman et al. 1991)

The community has strong affinity with Jarmans rainforest type but the presence of wet sclerophyll elements distinguish it. The community is restricted to narrow gullies and stream confluences. Typically, however, it is also restricted in its extent along the length of creeks only occurring sporadically in the most sheltered parts of gullies. The community is dominated by *Nothofagus cunninghamii* and *Atherosperma moschatum* up to 20m tall. The *Nothofagus cunninghamii* are either multi-stemmed or single-stemmed indicating both vegetative and seed regeneration after disturbance, probably by fire. *Pomaderris apetala* and *Olearia argophylla* often reach subdominance while *Beyeria viscosa* and *Pittosporum bicolor* are common below them. *Zieria arborescens* and *Bursaria spinosa* are occasional adventive species. The shrub layer supports *Coprosma quadrifida*, *Aristotelia peduncularis*, *Correa lawrenciana*, *Prostanthera lasianthos*. The fern flora is rich and commonly includes *Histiopteris incisa*, *Blechnum wattsii*, *B. nudum*, *Tmesipteris billardieri*, *Dicksonia antarctica*, *Microsorium diversifolium*, *Rumohra adiantiformis*, *Ctenopteris heterophylla*, *Hypolepis rugosula*, *Grammitis magellanica*, *G. billardieri*, *Polyphlebium venosum*, *Sticherus tener*, *Hymenophyllum rarum*, *H. flabellatum*, *H. cupressiforme* and *Asplenium bulbiferum*.

#### O. Riverine scrub

The eastern and northern limits of the study area are bounded by the Mersey River along which a narrow strip of riparian vegetation exists. The soil is recent alluvium. Much of the length of this strip exists on private agricultural land and has consequently been modified. The native community is fairly homogeneous along the eastern section of the river and is most commonly dominated by *Eucalyptus viminalis* but occasionally by either *E. amygdalina* or *E. obliqua*. The most common subdominant tree species are *Pomaderris apetala*, *Acacia verticillata*, *A. dealbata*, *Leptospermum lanigerum*, *Callistemon pallidus*, *Bursaria spinosa* and *Notelaea ligustrina*. The most common shrubs are *Bossiaea riparia*, *Lomatia tinctoria* and the scrambling shrub *Hibbertia empetrifolia*. Also commonly seen are *Tasmannia lanceolata*, *Grevillea australis*, *Correa lawrenciana*, *Bauera rubioides*, *Pimelea nivea* and *Melaleuca squarrosa*. *Lepidosperma elatius* and *Gahnia grandis* occasionally dominate the shrublayer. Ferns tend to be confined to the bank of the river and include *Blechnum nudum*, *B. wattsii*, *B. minus*, *B. fluviatile*, *Adiantum aethiopicum* and *Dicksonia antarctica*.

Rarer and sporadic components include *Aristotelia peduncularis*, *Pomaderris pilifera*, *P. phyllicifolia*, *Pittosporum bicolor*, *Epacris exserta*, *Prostanthera lasianthos*, *Carex appressa*, *Juncus subsecundus* and *Stylium graminifolium*.

The narrow width of this and most riparian strips results in such communities often containing adventive species due to edge effect from the adjoining communities. In this case those species include *Pultenaea juniperina*, *P. gunnii*, *Pteridium esculentum*, *Olearia lirata* and *Lomandra longifolia*.

#### **P. Heathy scrub**

*Eucalyptus amygdalina* dominates this scrub as a low sparse woodland. The community occurs on the slopes immediately below the conglomerate rock faces in the south west of the study area. The substrate is sandy with occasional large conglomerate boulders scattered throughout. Although the catchment faces north, its considerable size and position below the main water-shed ameliorates the effect of drought in this community. *Leptospermum scoparium* and *L. glaucescens* completely dominate the scrub component of the community with *Banksia marginata* frequent but more scattered. Other species which are common and occur throughout are *Aotus ericoides*, *Leucopogon collinus*, *L. ericoides* and *Epacris impressa*. *Amperia xiphoclada* and *Xanthosia pilosa* are more sparse.

The community has been burnt in patches at different times and this is evident by the different heights of the scrub but also by the presence of small herbs in the early successional phases. Most notable are *Stylium graminifolium*, *Tetratheca glandulosa* and *Gonocarpus teucrioides*. On the margins of this scrub the community becomes a tall open heath as it grades into *Eucalyptus amygdalina* heathy woodland. Species that appear in this ecotone include *Monotoca glauca*, *Acacia mucronata* and *Banksia marginata* as subdominant trees. *Boronia pilosa*, *Persoonia juniperina* and *Hibbertia procumbens* enter as common shrubs, while *Lycopodium deuterodensum*, *Xyris operculata* and *Drosera auriculata* produce a very sparse ground layer.

#### **Q. Buttongrass Moorland. Common Wet Eastern Heathy** (Jarman *et al.* 1988)

This community is most commonly found in the north-east, north-west and far south of the state. It is restricted in distribution in the study area to poorly drained locations at the foot of the conglomerate talus fan and also occurs on top of the range on the poorly drained narrow plateau. The unit in the study area was too small to map. The community is generally quite variable (Jarman *et al.* 1988) and in this instance occurs beneath sparse *Eucalyptus amygdalina*, one of the less common dominants of this community type. *Melaleuca squamea* and *Leptospermum glaucescens* form a medium canopy in which *Banksia marginata* and *Leptospermum scoparium* are common. The moorland component supports abundant *Gymnoschoenus sphaerocephalus* as pedestals up to 80 cm tall. Shrubs include *Aotus ericoides*, *Epacris lanuginosa* and *E. impressa* all of which are common. Common sedges are represented by *Empodisma minus*, *Xyris operculata* and *Schoenus tenuissimus* and the ferns by *Gleichenia dicarpa* and *Pteridium esculentum*, the former producing a dense but patchy cover.

#### **R. Rockface heathy scrub**

The northern face of the Gog Range features broken cliff-lines in conglomerate. This part of the landscape supports also supports sparse *Eucalyptus amygdalina* of poor form. However, *Leptospermum scoparium* and *L. glaucescens* form extensive scrubs on ridges and in gullies. The heath species *Epacris impressa*, *Aotus ericoides*, *Xanthosia pilosa*, *Leucopogon ericoides*, *L. collinus* and *Pentachondra involucrata* are common but form only a sparse cover. *Oxylobium arborescens* is frequent and may become subdominant to *E. amygdalina* over *Pteridium esculentum* on loose talus. *Monotoca glauca* is subdominant on soil pediments immediately below the cliffs. *Dianella tasmanica* and *Dianella revoluta* occur in wetter and drier sites respectively while *Lomandra longifolia* is also on soil pediments at the base of the rocks. *Microsorium diversifolium* and *Asplenium flabellifolium* are occasional amongst mosses in rock crevices. The grasses *Poa rodwayi*, *P. tenera* and *Deyeuxia monticola* are also scattered but may also dominate small areas. The orchids *Caladenia* sp. and *Paracaleana minor* are rare but regular.

Table 1. A list of all of the communities recorded in the study area, their known conservation status and reserves containing them.

## Species of Considerable Conservation Significance.

### KEY TO CODES

Risk Code		NATIONAL (modified from Briggs & Leigh, 1988)	
STATE			
Endangered	e	Endangered	E
Extinct	x	Extinct	X
Probably extinct	x?	Rare	R
Unknown	k	Unknown	K
Unreserved	u	Vulnerable	V
Vulnerable	v		
Endemic		EN	

*Desmodium varians* var. *gunnii* is listed as **unreserved** and **vulnerable uv**, that is, it is likely to become extinct in Tasmania over the longer period if current land clearing and landuse practices continue. It is restricted to the grassy areas in shrubby *E. amygdalina* forest adjacent to the private land (Quadrat 442) in the north east. Although the area is fenced it does appear to be grazed by domestic stock. The Fabaceae family in which *Desmodium* belongs is well known for its palatability to grazers and as such grazing of the area by domestic stock should be actively discouraged immediately. A more sparse population was recorded in quadrat 35, within the proposed logging coupe number 1, also in *E. amygdalina* forest.

*Goodia pubescens* is a widespread species but is currently **unreserved**. The plant was only recorded in one quadrat in the study area which may be its only occurrence in the study site (Quadrat 444). The position is steep and adjacent to a creekline in shrubby *E. obliqua* forest.

*Blechnum patersonii* had previously been reported from the Eel Hole Creek catchment (Williams 1987). During the present survey two additional sites in the same creekline were recorded. One in particular is a large and vigorous part of the population on the eastern bank of the creek (Quadrat 36). The species is considered as **rare** in Tasmania being recorded in less than twenty 10 X 10 km mapping grid squares. Its conservation status is therefore coded as **r2**. The species was also recorded in quadrats 30 and 38.

The grass species *Poa tenera* is currently **poorly reserved** being recorded in only one secure reserve, Freycinet National Park. The species was found across a broad range in the study area from *Eucalyptus amygdalina* shrubby forest to *E. viminalis* 0100 wet sclerophyll forest. The plant is not abundant occurring only as sparse individuals.

*Phyllota diffusa* is assigned an **r2** rarity status. This species is restricted in its east coast distribution but occurs all down the west coast (pers. comm M. Cameron). Only one other inland population has been reported but no collection was made, that distribution is in the north east. The species is located in (quadrat 214), heathy *E. amygdalina* forest.

**Poa sp nova** The taxonomy of the material collected is not clear at this stage. It is not a species recorded in Tasmania (D. Morris pers. com.). However, a more thorough search of mainland records is required to be certain of its status. The specimens were collected from quadrats 315, 316 and 317. The latter two sites being on conglomerate cliffs, this is not a common habitat in Tasmania.

**Pimelea curviflora** var. *gracilis* Although this species was located in 7 quadrats (39, 430, 310, 432, 243, 14, 321) in all but quadrat 39 it was a rare plant. Quadrat 39 is in the proposed logging coupe 1. The taxonomy of this species has recently been reviewed in the

Flora of Australia. The Tasmanian flora recognized *Pimelea curviflora* ssp. *gracilis* and *micrantha* and 1 var. *sericea*. However, the Flora of Australia now indicates ssp. *curviflora* includes the var. *gracilis*. The ssp. *micrantha* has been assigned species recognition. *P. curviflora* var. *sericea* is still distinguished. *P. curviflora* var. *gracilis* attracts a r2 rarity status and although it is found in three secure reserves, BS, CI and S all of these are Bass Strait islands, it remains unreserved on the Tasmanian mainland.

***Ajuga australis*** was recorded from only one site, in proposed logging coupe 1 (quadrat 39). The species has an r2 rarity status in Tasmania.

***Uncinea elegans* ?.** (not a positive identification) This species has an r1 rarity status being found in less than ten 10 km map grids. It is reserved in the South West National Park. The species was found in the riparian Myrtle-Musk Rainforest community in this survey and was rare.
